

Package ‘BosonSampling’

May 14, 2021

Type Package

Title Classical Boson Sampling

Version 0.1.3

Date 2021-11-07

Description Classical Boson Sampling using the algorithm of Clifford and Clifford (2017) <arXiv:1706.01260>. Also provides functions for generating random unitary matrices, evaluation of matrix permanents (both real and complex) and evaluation of complex permanent minors.

Maintainer Raphaël Clifford <clifford@cs.bris.ac.uk>

License GPL-2

Imports Rcpp (>= 0.12.12)

LinkingTo Rcpp, RcppArmadillo

Encoding latin1

NeedsCompilation yes

bosonSampler	<i>Function for independently sampling from the Boson Sampling distribution</i>
--------------	---

Description

The function implements the Boson Sampling algorithm defined in Clifford and Clifford (2017) <https://arxiv.org/abs/1706.01260>

Usage

```
bosonSampler(A, sampleSize, perm = FALSE)
```

Arguments

A	the first n columns of an (m x m) random unitary matrix, see randomUnitary
sampleSize	the number of independent sample values required for given A
perm	TRUE if the permanents and pmfs of each sample value are required

Details

Let the matrix A be the first n columns of an $(m \times m)$ random unitary matrix, then $X \leftarrow \text{bosonSampler}(A, \text{sampleSize} = N, \text{perm} = \text{TRUE})$ provides $X\$values$, $X\$perms$ and $X\$pmfs$,

The component $X\$values$ is an $(n \times N)$ matrix with columns that are independent sample values from the Boson Sampling distribution. Each sample value is a vector of n integer-valued output modes in random order. The elements of the vector can be sorted in increasing order to provide a multiset representation of the sample value.

The outputs $X\$perms$ and $X\$pmfs$ are vectors of the permanents and probability mass functions (pmfs) associated with the sample values. The permanent associated with a sample value $v = (v_1, \dots, v_n)$ is the permanent of an $(n \times n)$ matrix constructed with rows v_1, \dots, v_n of A . Note the constructed matrix, M , may have repeated rows since v_1, \dots, v_n are not necessarily distinct. The pmf is calculated as $\text{Mod}(pM)^2 / \text{prod}(\text{factorial}(\text{tabulate}(c)))$ where pM is the permanent of M .

Value

$X = \text{bosonSampler}(A, \text{sampleSize} = N, \text{perm} = \text{TRUE})$ provides $X\$values$, $X\$perms$ and $X\$pmfs$. See Details.

Examples

```
set.seed(7)
n <- 20 # number of photons
m <- 200 # number of output modes
A <- randomUnitary(m)[,1:n]
# sample of output vectors
valueList <- bosonSampler(A, sampleSize = 10)$values
valueList
# sample of output multisets
apply(valueList,1, sort)
#
set.seed(7)
n <- 12 # number of photons
m <- 30 # number of output modes
A <- randomUnitary(m)[,1:n]
# sample of output vectors
valueList = bosonSampler(A, sampleSize = 1000)$values
# Compare frequency of output modes at different
# positions in the output vectors
matplot(1:m,apply(valueList,1,tabulate), pch =20, t = "p",
xlab = "output modes", ylab = "frequency")
```

Description

These three functions are used in the classical Boson Sampling problem

Usage

```
cxPerm(A)
rePerm(B)
cxPermMinors(C)
```

Arguments

A	a square complex matrix.
B	a square real matrix.
C	a rectangular complex matrix where $nrow(C) = ncol(C) + 1$.

Details

Permanents are evaluated using Glynn's formula (equivalently that of Nijenhuis and Wilf (1978))

Value

`cxPerm(A)` returns a complex number: the permanent of the complex matrix A.
`rePerm(B)` returns a real number: the permanent of the real matrix B.
`cxPermMinors(C)` returns a complex vector of length $ncol(C)+1$: the permanents of all $ncol(C)$ -dimensional square matrices constructed by removing individual rows from C.

Examples

```
set.seed(7)
n <- 20
A <- randomUnitary(n)
cxPerm(A)
#
B <- Re(A)
rePerm(B)
#
C <- A[, -n]
```

```
v <- cxPermMinors(C)
#
# Check Laplace expansion by sub-permanents
c(cxPerm(A),sum(v*A[,n]))
```

randomUnitary	<i>Random unitary</i>
---------------	-----------------------

Description

Returns a square complex matrix sampled from the Haar random unitary distribution.

Usage

```
randomUnitary(size)
```

Arguments

size dimension of matrix

Value

A square complex matrix.

Examples

```
m <- 25 # size of matrix (m x m)
set.seed(7)
U <- randomUnitary(m)
#
n <- 5 # First n columns
A <- U[,1:n]
```
