

Package ‘logistf’

May 8, 2026

Version 1.26.1

Date 2025-04-16

Title Firth's Bias-Reduced Logistic Regression

Depends R (>= 3.0.0)

Imports mice, mgcv, formula.tools, Matrix

Suggests emmeans (>= 1.4), estimability

Description Fit a logistic regression model using Firth's bias reduction method, equivalent to penalization of the log-likelihood by the Jeffreys prior. Confidence intervals for regression coefficients can be computed by penalized profile likelihood. Firth's method was proposed as ideal solution to the problem of separation in logistic regression, see Heinze and Schemper (2002) <doi:10.1002/sim.1047>. If needed, the bias reduction can be turned off such that ordinary maximum likelihood logistic regression is obtained. Two new modifications of Firth's method, FLIC and FLAC, lead to unbiased predictions and are now available in the package as well, see Pühr et al (2017) <doi:10.1002/sim.7273>.

logistf-package

Firth's Bias-Reduced Logistic Regression

Description

Fits a binary logistic regression model using Firth's bias reduction method, and its modifications FLIC and FLAC, which both ensure that the sum of the predicted probabilities equals the number of events. If needed, the bias reduction can be turned off such that ordinary maximum likelihood logistic regression is obtained.

Details

The package `logistf` provides a comprehensive tool to facilitate the application of Firth's correction for logistic regression analysis, including its modifications FLIC and FLAC.

The call of the main function of the library follows the structure of the standard functions as `lm` or `glm`, requiring a `data.frame` and a formula for the model specification. The resulting object belongs to the new class `logistf`, which includes penalized maximum likelihood (Firth-Logistic'- or FL'-type) logistic regression parameters, standard errors, confidence limits, p-values, the value of the maximized penalized log likelihood, the linear predictors, the number of iterations needed to arrive

at the maximum and much more. Furthermore, specific methods for the resulting object are supplied. Additionally, a function to plot profiles of the penalized likelihood function and a function to perform penalized likelihood ratio tests have been included.

In explaining the details of the estimation process we follow mainly the description in Heinze & Ploner (2003). In general, maximum likelihood estimates are often prone to small sample bias. To reduce this bias, Firth (1993) suggested to maximize the penalized log likelihood $\log L(\beta)^* = \log L(\beta) + 1/2 \log |I(\beta)|$, where $I(\beta)$ is the Fisher information matrix, i. e. minus the second derivative of the log likelihood. Applying this idea to logistic regression, the score function $U(\beta)$ is replaced by the modified score function $U(\beta)^* = U(\beta) + a$, where a has r th entry $a_r = 0.5 \text{tr} I(\beta)^{-1} [dI(\beta)/d\beta_r]$, $r = 1, \dots, k$. Heinze and Schemper (2002) give the explicit formulae for $I(\beta)$ and $I(\beta)/d\beta_r$.

In our programs estimation of β can be based on a Newton-Raphson algorithm or on iteratively reweighted least squares. Parameter values are initialized usually with 0, but in general the user can specify arbitrary starting values.

With a starting value of $\beta^{(0)}$, the penalized maximum likelihood estimate β is obtained iteratively via Newton-Raphson:

$$\beta^{(s+1)} = \beta^{(s)} + I(\beta^{(s)})^{-1} U(\beta^{(s)})^*$$

If the penalized log likelihood evaluated at $\beta^{(s+1)}$ is less than that evaluated at $\beta^{(s)}$, then $\beta^{(s+1)}$ is recomputed by step-halving. For each entry r of β with $r = 1, \dots, k$ the absolute step size $|\beta_r^{(s+1)} - \beta_r^s|$ is restricted to a maximal allowed value `maxstep`. These two means should avoid numerical problems during estimation. The iterative process is continued until the parameter estimates converge, i. e., until three criteria are met: the change in log likelihood is less than `lconv`, the maximum absolute element of the score vector is less than `gconv`, the maximum absolute change in beta is less than `xconv`. `lconv`, `gconv`, `xconv` can be controlled by `control=logistf.control(lconv=..., gconv=..., xconv=...)`.

Computation of profile penalized likelihood confidence intervals for parameters (`logistpl`) follows the algorithm of Venzon and Moolgavkar (1988). For testing the hypothesis of $\gamma = \gamma_0$, let the likelihood ratio statistic

$$LR = 2[\log L(\gamma, \delta) - \log L(\gamma_0, \delta_{\gamma_0})^*]$$

where (γ, δ) is the joint penalized maximum likelihood estimate of $\beta = (\gamma, \delta)$, and δ_{γ_0} is the penalized maximum likelihood estimate of δ when $\gamma = \gamma_0$. The profile penalized likelihood confidence interval is the continuous set of values γ_0 for which LR does not exceed the $(1 - \alpha)100$ th percentile of the χ_1^2 -distribution. The confidence limits can therefore be found iteratively by approximating the penalized log likelihood function in a neighborhood of β by the quadratic function

$$l(\beta + \delta) = l(\beta) + \delta' U^* - 0.5 \delta' I \delta$$

where $U^* = U(\beta)^*$ and $-I = -I(\beta)$.

In some situations computation of profile penalized likelihood confidence intervals may be time consuming since the iterative procedure outlined above has to be repeated for the lower and for the upper confidence limits of each of the k parameters. In other problems one may not be interested in interval estimation, anyway. In such cases, the user can request computation of Wald confidence intervals and P-values, which are based on the normal approximation of the parameter estimates and do not need any iterative estimation process. Note that from version 1.24.1 on, the variance-covariance matrix is based on the second derivative of the likelihood of the augmented data rather

than the original data, which proved to be a better approximation if the user chooses to set a higher value for τ , the penalty strength.

The adequacy of Wald confidence intervals for parameter estimates can be verified by plotting the profile penalized log likelihood (PPL) function. A symmetric shape of the PPL function allows use of Wald intervals, while an asymmetric shape demands profile penalized likelihood intervals (Heinze & Schemper (2002)). Further documentation can be found in Heinze & Ploner (2004).

The package includes functions to work with multiply imputed data sets, such as generated by the mice package. Results on individual fits can be pooled to obtain point and interval estimates, as well as profile likelihood confidence intervals and likelihood profiles in general (Heinze, Ploner and Beyea, 2013).

Moreover, in the package the modifications FLIC and FLAC have been implemented, which were described in Puhr et al (2017) as solutions to obtain accurate predicted probabilities.

 add1.logistf

Add or Drop All Possible Single Terms to/from a logistf Model

Description

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

Usage

```
## S3 method for class 'logistf'
add1(object, scope, data, test = "PLR", ...)
```

Arguments

object	A fitted logistf, flic or flac object
scope	The scope of variables considered for adding or dropping. Should be a vector of variable names. Can be left missing; the method will then use all variables in the object's data slot which are not identified as the response variable.
data	The data frame used to fit the object.
test	The type of test statistic. Currently, only the PLR test (penalized likelihood ratio test) is allowed for logistf fits.
...	Further arguments passed to or from other methods.

Details

drop1 and add1 generate a table where for each variable the penalized likelihood ratio chi-squared, the degrees of freedom, and the p-value for dropping/adding this variable are given.

Value

A matrix with nvar rows and 3 columns (Chisquared, degrees of freedom, p-value).

Examples

```
data(sex2)
fit<-logistf(data=sex2, case~1, pl=FALSE)
add1(fit, scope=c("dia", "age"), data=sex2)

fit2<-logistf(data=sex2, case~age+oc+dia+vic+vicl+vis)
drop1(fit2, data=sex2)
```

 anova.logistf

Analysis of Penalized Deviance for logistf Models

Description

This method compares hierarchical and non-hierarchical logistf models using penalized likelihood ratio tests. It replaces the function logistftest of former versions of logistf.

Usage

```
## S3 method for class 'logistf'
anova(object, fit2, formula, method = "nested", ...)
```

Arguments

object	A fitted logistf model object
fit2	Another fitted logistf model object, to be compared with object
formula	Alternatively to fit2, a formula which specifies terms to omit from the object model fit.
method	One of c("nested","PLR"). nested is the default for hierarchically nested models, and will compare the penalized likelihood ratio statistics (minus twice the difference between maximized penalized log likelihood and null penalized log likelihood), where the null penalized log likelihood is computed from the same, hierarchically superior model. Note that unlike in maximum likelihood analysis, the null penalized likelihood depends on the penalty (Jeffreys prior) which itself depends on the scope of variables of the hierarchically superior model. PLR compares the difference in penalized likelihood ratio between the two models, where for each model the null penalized likelihood is computed within the scope of variables in that model. For PLR, the models need not be hierarchically nested.
...	Further arguments passed to the method.

Details

Comparing models fitted by penalized methods, one must consider that the penalized likelihoods are not directly comparable, since a penalty is involved. Or in other words, inserting zero for some regression coefficients will not lead to the same penalized likelihood as if the corresponding variables are simply "unknown" to a model. The anova method takes care that the same penalty is used for two hierarchically nested models, and if the models are not hierarchically nested, it will first relate each penalized likelihood to its null penalized likelihood, and only compare the resulting penalized likelihood ratio statistics. The chi-squared approximation for this latter method (PLR) is considered less accurate than that of the nested method. Nevertheless, it is the only way to go for comparison of non-nested models.

Value

An object of class `anova.logistf` with items

<code>chisq</code>	the chisquared statistic for the model comparison
<code>df</code>	The degrees of freedom
<code>pval</code>	The p-value
<code>call</code>	The function call
<code>method</code>	The method of comparison (input)
<code>model1</code>	The first model
<code>model2</code>	The second model which was compared to the first model
<code>PLR1</code>	The PLR statistic of the first model
<code>PLR2</code>	the PLR statistic of the second model; for the nested method, this will be the drop in chi-squared due to setting the coefficients to zero

Examples

```
data(sex2)
fit<-logistf(data=sex2, case~age+oc+dia+vic+vicl+vis)

#simultaneous test of variables vic, vicl, vis:
anova(fit, formula=~vic+vicl+vis)

#test versus a simpler model
fit2<-logistf(data=sex2, case~age+oc+dia)
# or: fit2<-update(fit, case~age+oc+dia)
anova(fit,fit2)

# comparison of non-nested models (with different df):
fit3<-logistf(data=sex2, case~age+vic+vicl+vis)
anova(fit2,fit3, method="PLR")
```

backward	<i>Backward Elimination/Forward Selection of Model Terms in logistf Models</i>
----------	--

Description

These functions provide simple backward elimination/forward selection procedures for logistf models.

Usage

```
backward(object, ...)  
  
## S3 method for class 'logistf'  
backward(  
  object,  
  scope,  
  data,  
  steps = 1000,  
  slstay = 0.05,  
  trace = TRUE,  
  printwork = FALSE,  
  full.penalty = FALSE,  
  ...  
)  
  
## S3 method for class 'flic'  
backward(  
  object,  
  scope,  
  steps = 1000,  
  slstay = 0.05,  
  trace = TRUE,  
  printwork = FALSE,  
  full.penalty = FALSE,  
  ...  
)  
  
forward(object, ...)  
  
## S3 method for class 'logistf'  
forward(  
  object,  
  scope,  
  data,  
  steps = 1000,  
  slentry = 0.05,  
  trace = TRUE,  
  printwork = FALSE,  
  pl = TRUE,  
  ...  
)
```

Arguments

object	A fitted logistf model object. To start with an empty model, create a model fit with a formula= y~1, pl=FALSE. (Replace y by your response variable.)
...	Further arguments to be passed to methods.

scope	The scope of variables to add/drop from the model. Can be missing for backward, backward will use the terms of the object fit. Alternatively, an arbitrary vector of variable names can be given, to allow that only some of the variables will be competitively selected or dropped. Has to be provided for forward.
data	The data frame used to fit the object.
steps	The number of forward selection/backward elimination steps.
slstay	For backward, the significance level to stay in the model.
trace	If TRUE, protocols selection steps.
printwork	If TRUE, prints each working model that is visited by the selection procedure.
full.penalty	If TRUE penalty is not taken from current model but from start model.
slentry	For forward, the significance level to enter the model.
pl	For forward, computes profile likelihood confidence intervals for the final model if TRUE.

Details

The variable selection is simply performed by repeatedly calling `add1` or `drop1` methods for `logistf`, and is based on penalized likelihood ratio test.

Note that selecting among factor variables is not supported. One way to use forward or backward with factor variables is to first convert them into numeric variables (0/1 coded dummy variables, choosing a sensible reference category). Forward and backward will then perform selection on the dummy variables, meaning that it will collapse levels of a factor variable with similar outcomes.

Value

An updated `logistf`, `flic` or `flac` fit with the finally selected model.

Functions

- `forward()`: Forward Selection

Examples

```
data(sex2)
fit<-logistf(data=sex2, case~1, pl=FALSE)
fitf<-forward(fit, scope=c("dia", "age"), data=sex2)

fit2<-logistf(data=sex2, case~age+oc+vic+vicl+vis+dia)
fitb<-backward(fit2, data=sex2)
```

CLIP.confint

*Confidence Intervals after Multiple Imputation: Combination of Likelihood Profiles***Description**

This function implements the new combination of likelihood profiles (CLIP) method described in Heinze, Ploner and Beyea (2013). This method is useful for computing confidence intervals for parameters after multiple imputation of data sets, if the normality assumption on parameter estimates and consequently the validity of applying Rubin's rules (pooling of variances) is in doubt. It consists of combining the profile likelihoods into a posterior. The function CLIP.confint searches for those values of a regression coefficient, at which the cumulative distribution function of the posterior is equal to the values specified in the argument ci.level (usually 0.025 and 0.975). The search is performed using R's optimize function.

Usage

```
CLIP.confint(
  obj = NULL,
  variable = NULL,
  data,
  firth = TRUE,
  weightvar = NULL,
  control = logistf.control(),
  ci.level = c(0.025, 0.975),
  pvalue = TRUE,
  offset = NULL,
  bound.lo = NULL,
  bound.up = NULL,
  legacy = FALSE
)
```

Arguments

obj	Either a list of logistf fits (on multiple imputed data sets), or the result of analysis of a mice (multiply imputed) object using with.mids
variable	The variable of interest, for which confidence intervals should be computed. If missing, confidence intervals for all variables will be computed.
data	A list of data set corresponding to the model fits. Can be left blank if obj was obtained with the dataout=TRUE option or if obj was obtained by mice
firth	If TRUE, applies the Firth correction. Should correspond to the entry in obj.
weightvar	An optional weighting variable for each observation.
control	Control parameters for logistf, usually obtained by logistf.control()
ci.level	The two confidence levels for each tail of the posterior distribution.
pvalue	If TRUE, will also compute a P-value from the posterior.

offset	An optional offset variable
bound.lo	Bounds (vector of length 2) for the lower limit. Can be left blank. Use only if problems are encountered.
bound.up	Bounds (vector of length 2) for the upper limit. Can be left blank. Use only if problems are encountered.
legacy	If TRUE, will use pure R code for all model fitting. Can be slow. Not recommended.

Details

For each confidence limit, this function performs a binary search to evaluate the combined posterior, which is obtained by first transforming the imputed-data likelihood profiles into cumulative distribution functions (CDFs), and then averaging the CDFs to obtain the CDF of the posterior. Usually, the binary search manages to find the confidence intervals very quickly. The number of iterations (mean and maximum) will be supplied in the output object. Further details on the method can be found in Heinze, Ploner and Beyea (2013).

Value

An object of class `CLIP.confint`, with items:

variable	The variable(s) which were analyzed
estimate	The pooled estimate (average over imputations)
ci	The confidence interval(s)
pvalue	The p-value(s)
imputations	The number of imputed datasets
ci.level	The confidence level (input)
bound.lo	The bounds used for finding the lower confidence limit; usually not of interest. May be useful for error-tracing.
bound.up	The bounds used for finding the upper confidence limit
iter	The number of iterations (for each variable and each tail)
call	The call object

Examples

```

#generate data set with NAs
freq=c(5,2,2,7,5,4)
y<-c(rep(1,freq[1]+freq[2]), rep(0,freq[3]+freq[4]), rep(1,freq[5]), rep(0,freq[6]))
x<-c(rep(1,freq[1]), rep(0,freq[2]), rep(1,freq[3]), rep(0,freq[4]),
rep(NA,freq[5]),rep(NA,freq[6]))
toy<-data.frame(x=x,y=y)

# impute data set 5 times
set.seed(169)
toymi<-list(0)
for(i in 1:5){
  toymi[[i]]<-toy
  y1<-toymi[[i]]$y==1 & is.na(toymi[[i]]$x)
  y0<-toymi[[i]]$y==0 & is.na(toymi[[i]]$x)
  xnew1<-rbinom(sum(y1),1,freq[1]/(freq[1]+freq[2]))
  xnew0<-rbinom(sum(y0),1,freq[3]/(freq[3]+freq[4]))
  toymi[[i]]$x[y1==TRUE]<-xnew1
  toymi[[i]]$x[y0==TRUE]<-xnew0
}

# logistf analyses of each imputed data set
fit.list<-lapply(1:5, function(X) logistf(data=toymi[[X]], y~x, pl=TRUE))

# CLIP confidence limits
CLIP.confint(obj=fit.list, data = toymi)

```

CLIP.profile

Combine Profile Likelihoods from Imputed-Data Model Fits

Description

This function uses CLIP (combination of likelihood profiles) to compute the pooled profile of the posterior after multiple imputation.

Usage

```

CLIP.profile(
  obj = NULL,
  variable,
  data,
  which,
  firth = TRUE,
  weightvar,
  control = logistf.control(),
  offset = NULL,
  from = NULL,
  to = NULL,

```

```

    steps = 101,
    legacy = FALSE,
    keep = FALSE
  )

```

Arguments

obj	Either a list of <code>logistf</code> fits (on multiple imputed data sets), or the result of analysis of a <code>mice</code> (multiply imputed) object using <code>with.mids</code> .
variable	The variable of interest, for which confidence intervals should be computed. If missing, confidence intervals for all variables will be computed.
data	A list of data set corresponding to the model fits. Can be left blank if <code>obj</code> was obtained with the <code>dataout=TRUE</code> option or if <code>obj</code> was obtained by <code>mice</code> .
which	Alternatively to <code>variable</code> , the argument <code>which</code> allows to specify the variable to compute the profile for as righthand formula, e.g. <code>which=~X</code> .
firth	If <code>TRUE</code> , applies the Firth correction. Should correspond to the entry in <code>obj</code> .
weightvar	An optional weighting variable for each observation
control	control parameters for <code>logistf</code> , usually obtained by <code>logistf.control()</code>
offset	An optional offset variable
from	Lowest value for the sequence of values for the regression coefficients for which the profile will be computed. Can be left blank.
to	Highest value for the sequence of values for the regression coefficients for which the profile will be computed. Can be left blank
steps	Number of steps for the sequence of values for the regression coefficients for which the profile will be computed
legacy	If <code>TRUE</code> , only R code will be used. Should be avoided.
keep	If <code>TRUE</code> , keeps the profiles for each imputed data sets in the output object.

Details

While `CLIP.confint` iterates to find those values at which the CDF of the pooled posterior equals the confidence levels, `CLIP.profile` will evaluate the whole profile, which enables plotting and evaluating the skewness of the combined and the completed-data profiles. The combined and completed-data profiles are available as cumulative distribution function (CDF) or in the scaling of relative profile likelihood (minus twice the likelihood ratio statistic compared to the maximum). Using a plot method, the pooled posterior can also be displayed as a density.

Value

An object of class `CLIP.profile` with items:

beta	The values of the regression coefficient
cdf	The cumulative distribution function of the posterior
profile	The profile of the posterior

<code>cdf.matrix</code>	An imputations x steps matrix with the values of the completed-data CDFs for each beta
<code>profile.matrix</code>	An imputations x steps matrix with the values of the completed-data profiles for each beta
<code>call</code>	The function call

```

emmeans-logistf	<i>Emmeans support for logistf</i>
-----------------	------------------------------------

Description

Support for the emmeans package is available. See below for an example of using `emmeans::emmeans()` with a `logistf` object.

Examples

```
data(sex2)
fit<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sex2)

emmeans::emmeans(fit, ~age+dia)
```

flac	<i>FLAC - Firth's logistic regression with added covariate</i>
------	--

Description

`flac` implements Firth's bias-reduced penalized-likelihood logistic regression with added covariate.

Usage

```
flac(...)

## Default S3 method:
flac(
  formula,
  data,
  model = TRUE,
  control,
  modcontrol,
  weights,
  offset,
  na.action,
  pl = TRUE,
  plconf = NULL,
  ...
)

## S3 method for class 'logistf'
flac(lfobject, data, model = TRUE, ...)
```

Arguments

...	Further arguments passed to the method or <code>logistf</code> -call.
formula	A formula object, with the response on the left of the operator, and the model terms on the right. The response must be a vector with 0 and 1 or FALSE and TRUE for the outcome, where the higher value (1 or TRUE) is modeled.
data	A data frame containing the variables in the model.
model	If TRUE the corresponding components of the fit are returned.
control	Controls iteration parameter. Taken from <code>logistf</code> -object when specified. Otherwise default is <code>control=logistf.control()</code> .
modcontrol	Controls additional parameter for fitting. Taken from <code>logistf</code> -object when specified. Otherwise default is <code>logistf.mod.control()</code> .
weights	specifies case weights. Each line of the input data set is multiplied by the corresponding element of weights
offset	a priori known component to be included in the linear predictor
na.action	a function which indicates what should happen when the data contain NAs
p1	Specifies if confidence intervals and tests should be based on the profile penalized log likelihood (<code>p1=TRUE</code> , the default) or on the Wald method (<code>p1=FALSE</code>).
p1conf	specifies the variables (as vector of their indices) for which profile likelihood confidence intervals should be computed. Default is to compute for all variables.
lfoject	A fitted <code>logistf</code> object.

Details

FLAC is a simple modification of Firth's logistic regression which provides average predicted probabilities equal to the observed proportion of events, while preserving the ability to deal with separation. It has been described by Puhr et al (2017).

The modified score equations to estimate coefficients for Firth's logistic regression can be interpreted as score equations for ML estimates for an augmented data set. This data set can be created by complementing each original observation i with two pseudo-observations weighted by $h_i/2$ with unchanged covariate values and with response values set to $y = 0$ and $y = 1$ respectively. The basic idea of FLAC is to discriminate between original and pseudo-observations in the alternative formulation of Firth's estimation as an iterative data augmentation procedure. The following generic methods are available for 'flac's output object: `print`, `summary`, `coef`, `confint`, `anova`, `extractAIC`, `add1`, `drop1`, `profile`, `terms`, `nobs`, `predict`. Furthermore, `forward` and `backward` functions perform convenient variable selection. Note that `anova`, `extractAIC`, `add1`, `drop1`, `forward` and `backward` are based on penalized likelihood ratio tests.

Value

A flac object with components:

<code>coefficients</code>	The coefficients of the parameter in the fitted model.
<code>predict</code>	A vector with the predicted probability of each observation
<code>linear.predictors</code>	A vector with the linear predictor of each observation.

prob	The p-values of the specific parameters
ci.lower	The lower confidence limits of the parameter.
ci.upper	The upper confidence limits of the parameter.
call	The call object.
alpha	The significance level: 0.95
var	The variance-covariance-matrix of the parameters.
loglik	A vector of the (penalized) log-likelihood of the restricted and the full models.
n	The number of observations.
formula	The formula object.
augmented.data	The augmented dataset used
df	The number of degrees of freedom in the model.
method	depending on the fitting method 'Penalized ML' or Standard ML'. } \item{method.ci}{the method in file likelihood' or 'Wald', depending on the argument pl and plconf.
control	a copy of the control parameters.
modcontrol	a copy of the modcontrol parameters.
terms	the model terms (column names of design matrix).
model	if requested (the default), the model frame used.

Methods (by class)

- `flac(default)`: With formula and data
- `flac(logistf)`: With `logistf` object

Examples

```
#With formula and data:
data(sex2)
flac(case ~ age + oc + vic + vicl + vis + dia, sex2)

#With a logistf object:
lf <- logistf(formula = case ~ age + oc + vic + vicl + vis + dia, data = sex2)
flac(lf, data=sex2)
```

flic

*FLIC - Firth's logistic regression with intercept correction***Description**

flic implements Firth's bias-reduced penalized-likelihood logistic regression with intercept correction.

Usage

```
flic(...)

## Default S3 method:
flic(
  formula,
  data,
  model = TRUE,
  control,
  modcontrol,
  weights,
  offset,
  na.action,
  ...
)

## S3 method for class 'logistf'
flic(lfobject, model = TRUE, ...)
```

Arguments

...	Further arguments passed to the method or <code>logistf</code> -call.
formula	A formula object, with the response on the left of the operator, and the model terms on the right. The response must be a vector with 0 and 1 or FALSE and TRUE for the outcome, where the higher value (1 or TRUE) is modeled.
data	If using with formula, a data frame containing the variables in the model.
model	If TRUE the corresponding components of the fit are returned.
control	Controls iteration parameter. Taken from <code>logistf</code> -object when specified. Otherwise default is <code>control=logistf.control()</code> .
modcontrol	Controls additional parameter for fitting. Taken from <code>logistf</code> -object when specified. Otherwise default is <code>logistf.mod.control()</code> .
weights	specifies case weights. Each line of the input data set is multiplied by the corresponding element of weights
offset	a priori known component to be included in the linear predictor
na.action	a function which indicates what should happen when the data contain NAs
lfobject	A fitted <code>logistf</code> object.

Details

FLIC is a simple modification of Firth's logistic regression which provides average predicted probabilities equal to the observed proportion of events, while preserving the ability to deal with separation.

In general the average predicted probability in Firth's logistic regression is not equal to the observed proportion of events. Because the determinant of the Fisher-Information matrix is maximized for $\pi_i = \frac{1}{2}$ it is concluded that Firth's penalization tends to push the predicted probabilities towards one-half compared with ML-estimation. FLIC first applies Firth's logistic regression and then corrects the intercept such that the predicted probabilities become unbiased while keeping all other coefficients constant. The following generic methods are available for `flic`'s output object: `print`, `summary`, `coef`, `confint`, `anova`, `extractAIC`, `add1`, `drop1`, `profile`, `terms`, `nobs`, `predict`. Furthermore, `forward` and `backward` functions perform convenient variable selection. Note that `anova`, `extractAIC`, `add1`, `drop1`, `forward` and `backward` are based on penalized likelihood ratio tests.

Value

A `flic` object with components:

<code>coefficients</code>	The coefficients of the parameter in the fitted model.
<code>predict</code>	A vector with the predicted probability of each observation.
<code>linear.predictors</code>	A vector with the linear predictor of each observation.
<code>var</code>	The variance-covariance-matrix of the parameters.
<code>prob</code>	The p-values of the specific parameters.
<code>ci.lower</code>	The lower confidence limits of the parameter.
<code>ci.upper</code>	The upper confidence limits of the parameter.
<code>call</code>	The call object.
<code>alpha</code>	The significance level: 0.95.
<code>method</code>	depending on the fitting method 'Penalized ML' or 'Standard ML'. } \item{method.ci}{the method in file likelihood' or 'Wald', depending on the argument <code>pl</code> and <code>plconf</code> .
<code>df</code>	The number of degrees of freedom in the model.
<code>loglik</code>	A vector of the (penalized) log-likelihood of the restricted and the full models.
<code>n</code>	The number of observations.
<code>formula</code>	The formula object.
<code>control</code>	a copy of the control parameters.
<code>modcontrol</code>	a copy of the modcontrol parameters.
<code>terms</code>	the model terms (column names of design matrix).
<code>model</code>	if requested (the default), the model frame used.

Methods (by class)

- `flic(default)`: With formula and data
- `flic(logistf)`: With `logistf` object

lf <- logistf(formula = case ~ age + oc + vic + vicl + vis + dia, data = sex2)
flic(lf)
```

logistf

Firth's Bias-Reduced Logistic Regression

Description

Implements Firth's bias-Reduced penalized-likelihood logistic regression.

Usage

```
logistf(
  formula,
  data,
  pl = TRUE,
  alpha = 0.05,
  control,
  plcontrol,
  modcontrol,
  firth = TRUE,
  init,
  weights,
  na.action,
  offset,
  plconf = NULL,
  flic = FALSE,
  model = TRUE,
  ...
)
```

Arguments

formula	A formula object, with the response on the left of the operator, and the model terms on the right. The response must be a vector with 0 and 1 or FALSE and TRUE for the outcome, where the higher value (1 or TRUE) is modeled. It is possible to include contrasts, interactions, nested effects, cubic or polynomial splines and all S features as well, e.g. $Y \sim X1*X2 + ns(X3, df=4)$.
data	A data.frame where the variables named in the formula can be found, i. e. the variables containing the binary response and the covariates.
pl	Specifies if confidence intervals and tests should be based on the profile penalized log likelihood (pl=TRUE, the default) or on the Wald method (pl=FALSE).
alpha	The significance level ($1-\alpha$ the confidence level, 0.05 as default).
control	Controls iteration parameter. Default is <code>control= logistf.control()</code>
plcontrol	Controls Newton-Raphson iteration for the estimation of the profile likelihood confidence intervals. Default is <code>plcontrol= logistpl.control()</code>
modcontrol	Controls additional parameter for fitting. Default is <code>logistf.mod.control()</code>
firth	Use of Firth's penalized maximum likelihood (firth=TRUE, default) or the standard maximum likelihood method (firth=FALSE) for the logistic regression. Note that by specifying pl=TRUE and firth=FALSE (and probably a lower number of iterations) one obtains profile likelihood confidence intervals for maximum likelihood logistic regression parameters.
init	Specifies the initial values of the coefficients for the fitting algorithm
weights	specifies case weights. Each line of the input data set is multiplied by the corresponding element of weights
na.action	a function which indicates what should happen when the data contain NAs
offset	a priori known component to be included in the linear predictor
plconf	specifies the variables (as vector of their indices) for which profile likelihood confidence intervals should be computed. Default is to compute for all variables.
flic	If TRUE, intercept is altered such that the predicted probabilities become unbiased while keeping all other coefficients constant (see Puhr et al, 2017)
model	If TRUE the corresponding components of the fit are returned.
...	Further arguments to be passed to <code>logistf</code>

Details

`logistf` is the main function of the package. It fits a logistic regression model applying Firth's correction to the likelihood. The following generic methods are available for `logistf`'s output object: `print`, `summary`, `coef`, `vcov`, `confint`, `anova`, `extractAIC`, `add1`, `drop1`, `profile`, `terms`, `nobs`, `predict`. Furthermore, `forward` and `backward` functions perform convenient variable selection. Note that `anova`, `extractAIC`, `add1`, `drop1`, `forward` and `backward` are based on penalized likelihood ratios.

Value

The object returned is of the class `logistf` and has the following attributes:

<code>coefficients</code>	the coefficients of the parameter in the fitted model.
<code>alpha</code>	the significance level (1- the confidence level) as specified in the input.
<code>terms</code>	the column names of the design matrix
<code>var</code>	the variance-covariance-matrix of the parameters.
<code>df</code>	the number of degrees of freedom in the model.
<code>loglik</code>	a vector of the (penalized) log-likelihood of the restricted and the full models.
<code>iter</code>	A vector of the number of iterations needed in the fitting process for the null and full model.
<code>n</code>	the number of observations.
<code>y</code>	the response-vector, i. e. 1 for successes (events) and 0 for failures.
<code>formula</code>	the formula object.
<code>call</code>	the call object.
<code>terms</code>	the model terms (column names of design matrix).
<code>linear.predictors</code>	a vector with the linear predictor of each observation.
<code>predict</code>	a vector with the predicted probability of each observation.
<code>hat.diag</code>	a vector with the diagonal elements of the Hat Matrix.
<code>conv</code>	the convergence status at last iteration: a vector of length 3 with elements: last change in log likelihood, $\max(\text{abs}(\text{score vector}))$, max change in beta at last iteration.
<code>method</code>	depending on the fitting method 'Penalized ML' or Standard ML'. } \item{method.ci}{the method in file likelihood' or 'Wald', depending on the argument <code>pl</code> and <code>plconf</code> .
<code>ci.lower</code>	the lower confidence limits of the parameter.
<code>ci.upper</code>	the upper confidence limits of the parameter.
<code>prob</code>	the p-values of the specific parameters.
<code>pl.iter</code>	only if <code>pl==TRUE</code> : the number of iterations needed for each confidence limit.
<code>betahist</code>	only if <code>pl==TRUE</code> : the complete history of beta estimates for each confidence limit.
<code>pl.conv</code>	only if <code>pl==TRUE</code> : the convergence status (deviation of log likelihood from target value, last maximum change in beta) for each confidence limit.
<code>control</code>	a copy of the control parameters.
<code>modcontrol</code>	a copy of the modcontrol parameters.
<code>flic</code>	logical, is TRUE if intercept was altered such that the predicted probabilities become unbiased while keeping all other coefficients constant. According to input of <code>logistf</code> .
<code>model</code>	if requested (the default), the model frame used.
<code>na.action</code>	information returned by <code>model.frame</code> on the special handling of NAs

logistf.control

Control Parameters for logistf

Description

Sets parameters for iterations in Firth's penalized-likelihood logistic regression.

Usage

```

logistf.control(
  maxit = 25,
  maxhs = 0,
  maxstep = 5,
  lconv = 1e-05,
  gconv = 1e-05,
  xconv = 1e-05,
  collapse = TRUE,
  fit = "NR"
)

```

Arguments

maxit	The maximum number of iterations
maxhs	The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
maxstep	Specifies the maximum step size in the beta vector within one iteration. Set to -1 for infinite stepsize.
lconv	Specifies the convergence criterion for the log likelihood.
gconv	Specifies the convergence criterion for the first derivative of the log likelihood (the score vector).
xconv	Specifies the convergence criterion for the parameter estimates.
collapse	If TRUE, evaluates all unique combinations of x and y and collapses data set.
fit	Fitting method used. One of Newton-Raphson: "NR" or Iteratively reweighted least squares: "IRLS"

Details

`logistf.control()` is used by `logistf` and `logistftest` to set control parameters to default values. Different values can be specified, e. g., by `logistf(..., control=logistf.control(maxstep=1))`.

Value

<code>maxit</code>	The maximum number of iterations
<code>maxhs</code>	The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
<code>maxstep</code>	Specifies the maximum step size in the beta vector within one iteration.
<code>lconv</code>	Specifies the convergence criterion for the log likelihood.
<code>gconv</code>	Specifies the convergence criterion for the first derivative of the log likelihood (the score vector).
<code>xconv</code>	Specifies the convergence criterion for the parameter estimates.
<code>collapse</code>	If TRUE, evaluates all unique combinations of x and y and collapses data set.
<code>fit</code>	Fitting method used. One of Newton-Raphson: "NR" or Iteratively reweighted least squares: "IRLS"
<code>call</code>	The function call.

Examples

```
data(sexagg)
fit2<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sexagg, weights=COUNT,
control=logistf.control(maxstep=1))
summary(fit2)
```

`logistf.mod.control` *Controls additional parameters for logistf*

Description

Sets parameters for `logistf` calls.

Usage

```
logistf.mod.control(tau = 0.5, terms.fit = NULL)
```

Arguments

<code>tau</code>	Penalization parameter (default = 0.5)
<code>terms.fit</code>	A numeric vector of terms to fit. Intercept has to be included if needed.

Value

tau	Penalization parameter (default = 0.5)
terms.fit	A numeric vector of terms to fit. Intercept has to be included if needed.

Examples

```
data(sexagg)
fit2<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sexagg, weights=COUNT,
modcontrol=logistf.mod.control(terms.fit=c(1,2)))
summary(fit2)
```

logistftest	<i>Penalized likelihood ratio test</i>
-------------	--

Description

This function performs a penalized likelihood ratio test on some (or all) selected factors. The resulting object is of the class logistftest and includes the information printed by the proper print method.

Usage

```
logistftest(
  object,
  test,
  values,
  firth = TRUE,
  beta0,
  weights,
  control,
  modcontrol,
  ...
)
```

Arguments

object	A fitted logistf object
test	righthand formula of parameters to test (e.g. $\sim B + D - 1$). As default all parameter apart from the intercept are tested. If the formula includes -1, the intercept is omitted from testing. As alternative to the formula one can give the indexes of the ordered effects to test (a vector of integers). To test only the intercept specify $test = \sim .$ or $test = 1$.
values	Null hypothesis values, default values are 0. For testing the specific hypothesis $B1=1, B4=2, B5=0$ we specify $test = \sim B1+B4+B5-1$ and $values=c(1, 2, 0)$.

firth	Use of Firth's (1993) penalized maximum likelihood (firth=TRUE, default) or the standard maximum likelihood method (firth=FALSE) for the logistic regression. Note that by specifying pl=TRUE and firth=FALSE (and probably lower number of iterations) one obtains profile likelihood confidence intervals for maximum likelihood logistic regression parameters.
beta0	Specifies the initial values of the coefficients for the fitting algorithm
weights	Case weights
control	Controls parameters for iterative fitting
modcontrol	Controls additional parameter for fitting. Default is modcontrol of object.
...	further arguments passed to logistf.fit

Details

This function performs a penalized likelihood ratio test on some (or all) selected factors. The resulting object is of the class `logistftest` and includes the information printed by the proper print method. Further documentation can be found in Heinze & Ploner (2004). In most cases, the functionality of the `logistftest` function is replaced by `anova.logistf`, which is a more standard way to perform likelihood ratio tests. However, as shown in the example below, `logistftest` provides some specials such as testing against non-zero values. (By the way, `anova.logistf` calls `logistftest`.)

Value

The object returned is of the class `logistf` and has the following attributes:

testcov	A vector of the fixed values of each covariate; NA stands for a parameter which is not tested.
loglik	A vector of the (penalized) log-likelihood of the full and the restricted models. If the argument <code>beta0</code> not missing, the full model isn't evaluated
df	The number of degrees of freedom in the model
prob	The p-value of the test
call	The call object
method	Depending on the fitting method 'Penalized ML' or 'Standard ML'
beta	The coefficients of the restricted solution

logistftest(fit, test = ~ vic + vicl - 1, values = c(2, 0))
```

logistpl.control	<i>Control Parameters for logistf Profile Likelihood Confidence Interval Estimation</i>
------------------	---

Description

Sets parameters for modified Newton-Raphson iteration for finding profile likelihood confidence intervals in Firth's penalized likelihood logistic regression

Usage

```
logistpl.control(
  maxit = 100,
  maxhs = 0,
  maxstep = 5,
  lconv = 1e-05,
  xconv = 1e-05,
  ortho = FALSE,
  pr = FALSE
)
```

Arguments

maxit	The maximum number of iterations
maxhs	The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
maxstep	Specifies the maximum step size in the beta vector within one iteration. Set to -1 for infinite stepsize.
lconv	Specifies the convergence criterion for the log likelihood.
xconv	Specifies the convergence criterion for the parameter estimates.
ortho	Requests orthogonalization of variable for which confidence intervals are computed with respect to other covariates
pr	Request rotation of the matrix spanned by the covariates

Details

logistpl.control() is used by logistf to set control parameters to default values when computing profile likelihood confidence intervals. Different values can be specified, e. g., by logistf(..., control=logistf.control(maxstep=1)).

Value

maxit	The maximum number of iterations
maxhs	The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
maxstep	Specifies the maximum step size in the beta vector within one iteration.
lconv	Specifies the convergence criterion for the log likelihood.
xconv	Specifies the convergence criterion for the parameter estimates.
ortho	specifies if orthogonalization is requested.
pr	specifies if rotation is requested

Author(s)

Georg Heinze

Examples

```
data(sexagg)
fit2<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sexagg, weights=COUNT,
  plcontrol=logistpl.control(maxstep=1))
summary(fit2)
```

plot.logistf.profile plot *Method for logistf Likelihood Profiles*

Description

Provides the plot method for objects created by profile.logistf or CLIP.profile

Usage

```
## S3 method for class 'logistf.profile'
plot(
  x,
  type = "profile",
  max1 = TRUE,
  colmain = "black",
  colimp = "gray",
  plotmain = T,
  ylim = NULL,
  ...
)
```

Arguments

x	A profile.logistf object
type	Type of plot: one of c("profile", "cdf", "density")
max1	If type="density", normalizes density to maximum 1
colmain	Color for main profile line
colimp	color for completed-data profile lines (for logistf.profile objects that also carry the CLIP.profile class attribute)
plotmain	if FALSE, suppresses the main profile line (for logistf.profile objects that also carry the CLIP.profile class attribute)
ylim	Limits for the y-axis
...	Further arguments to be passed to plot().

Details

The plot method provides three types of plots (profile, CDF, and density representation of a profile likelihood). For objects generated by CLIP.profile, it also allows to show the completed-data profiles along with the pooled profile.

Value

The function is called for its side effects

```

predict.flac

Predict Method for flac Fits

Description

Obtains predictions from a fitted flac object.

Usage

```

## S3 method for class 'flac'
predict(
  object,
  newdata,
  type = c("link", "response", "terms"),
  se.fit = FALSE,
  ...
)

```

Arguments

object	A fitted object of class flac.
newdata	Optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.

type	The type of prediction required. The default is on the scale of the linear predictors. The alternative response gives the predicted probabilities. Type terms returns a matrix with the fitted values of each term in the formula on the linear predictor scale.
se.fit	If TRUE(default = FALSE) standard errors are computed.
...	further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit.

Value

A vector or matrix of predictions.

predict.flic	<i>Predict Method for flic Fits</i>
--------------	-------------------------------------

Description

Obtains predictions from a fitted flic object.

Usage

```
## S3 method for class 'flic'
predict(
  object,
  newdata,
  type = c("link", "response", "terms"),
  se.fit = FALSE,
  ...
)
```

Arguments

object	A fitted object of class flic.
newdata	Optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type	The type of prediction required. The default is on the scale of the linear predictors. The alternative response gives the predicted probabilities. Type terms returns a matrix with the fitted values of each term in the formula on the linear predictor scale.
se.fit	If TRUE(default = FALSE) standard errors are computed.
...	further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit.

Value

A vector or matrix of predictions

predict.logistf	<i>Predict Method for logistf Fits</i>
-----------------	--

Description

Obtains predictions from a fitted logistf object.

Usage

```
## S3 method for class 'logistf'
predict(
  object,
  newdata,
  type = c("link", "response", "terms"),
  flic = FALSE,
  se.fit = FALSE,
  reference,
  na.action = na.pass,
  ...
)
```

Arguments

object	A fitted object of class logistf.
newdata	Optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type	The type of prediction required. The default is on the scale of the linear predictors. The alternative response gives the predicted probabilities. Type terms returns a matrix with the fitted values of each term in the formula on the linear predictor scale.
flic	If TRUE(default = FALSE), predictions are computed with intercept correction.
se.fit	If TRUE(default = FALSE) standard errors are computed.
reference	A named vector of reference values for each variable for type="terms".
na.action	Function determining what should be done with missing values in newdata. The default is to predict NA.
...	further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit.

Value

A vector or matrix of predictions.

profile.logistf	<i>Compute Profile Penalized Likelihood</i>
-----------------	---

Description

Evaluates the profile penalized likelihood of a variable based on a logistf model fit

Usage

```
## S3 method for class 'logistf'
profile(
  fitted,
  which,
  variable,
  steps = 100,
  pitch = 0.05,
  limits,
  alpha = 0.05,
  firth = TRUE,
  legends = TRUE,
  control,
  plcontrol,
  ...
)
```

Arguments

fitted	An object fitted by logistf
which	A righthand formula to specify the variable for which the profile should be evaluated, e.g., which=~X).
variable	Alternatively to which, a variable name can be given, e.g., variable="X"
steps	Number of steps in evaluating the profile likelihood
pitch	Alternatively to steps, one may specify the step width in multiples of standard errors
limits	Lower and upper limits of parameter values at which profile likelihood is to be evaluated
alpha	The significance level (1- α the confidence level, 0.05 as default).

firth	Use of Firth's penalized maximum likelihood (firth=TRUE, default) or the standard maximum likelihood method (firth=FALSE) for the logistic regression.
legends	legends to be included in the optional plot
control	Controls Newton-Raphson iteration. Default is control= logistf.control(maxstep,maxit,maxhs, lconv, gconv, xconv)
plcontrol	Controls Newton-Raphson iteration for the estimation of the profile likelihood confidence intervals. Default is plcontrol= logistpl.control(maxstep, maxit, maxhs, lconv, xconv, ortho, pr)
...	Further arguments to be passed.

Value

An object of class `logistf.profile` with the following items:

beta	Parameter values at which likelihood was evaluated
stdbeta	Parameter values divided by standard error
profile	profile likelihood, standardized to 0 at maximum of likelihood. The values in profile are given as minus χ^2
loglik	Unstandardized profile likelihood
signed.root	signed root (z) of χ^2 values (negative for values below the maximum likelihood estimate, positive for values above the maximum likelihood estimate)
cdf	profile likelihood expressed as cumulative distribution function, obtained as $\Phi(z)$, where Φ denotes the standard normal distribution function.

Examples

```
data(sex2)
fit<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sex2)
plot(profile(fit,variable="dia"))
plot(profile(fit,variable="dia"), "cdf")
plot(profile(fit,variable="dia"), "density")
```

PVR.confint

*Pseudo Variance Modification of Rubin's Rule***Description**

The pseudo-variance modification proposed by Heinze, Ploner and Beyea (2013) provides a quick way to adapt Rubin's rules to situations of a non-normal distribution of a regression coefficient. However, the approximation is less accurate than that of the CLIP method.

Usage

```
PVR.confint(obj, variable, skewbeta = FALSE)
```

Arguments

obj	A fitted logisf object
variable	The variable(s) to compute the PVR confidence intervals, either provided as names or as numbers
skewbeta	If TRUE, incorporates information on the skewness of the parameter estimates across the imputed data sets.

Details

The pseudo-variance modification computes a lower and an upper pseudo-variance, which are based on the distance between profile likelihood limits and the parameter estimates. These are then plugged into the usual Rubin's rules method of variance combination

Value

An object of class `PVR.confint` with items:

estimate	the pooled parameter estimate(s) (the average across completed-data estimates)
ci	the confidence intervals based on the PVR method
lower.var	the lower pseudo-variance(s)
upper.var	the upper pseudo-variance(s)
conflev	the confidence level: this is determined by the confidence level (1-alpha) used in the input fit objects
call	the function call
variable	the variable(s) for which confidence intervals were computed

Examples

```
#generate data set with NAs
freq=c(5,2,2,7,5,4)
y<-c(rep(1,freq[1]+freq[2]), rep(0,freq[3]+freq[4]), rep(1,freq[5]), rep(0,freq[6]))
x<-c(rep(1,freq[1]), rep(0,freq[2]), rep(1,freq[3]), rep(0,freq[4]), rep(NA,freq[5]),
     rep(NA,freq[6]))
toy<-data.frame(x=x,y=y)

# impute data set 5 times
set.seed(169)
toymi<-list(0)
for(i in 1:5){
  toymi[[i]]<-toy
  y1<-toymi[[i]]$y==1 & is.na(toymi[[i]]$x)
  y0<-toymi[[i]]$y==0 & is.na(toymi[[i]]$x)
  xnew1<-rbinom(sum(y1),1,freq[1]/(freq[1]+freq[2]))
  xnew0<-rbinom(sum(y0),1,freq[3]/(freq[3]+freq[4]))
  toymi[[i]]$x[y1==TRUE]<-xnew1
  toymi[[i]]$x[y0==TRUE]<-xnew0
}

# logistf analyses of each imputed data set
fit.list<-lapply(1:5, function(X) logistf(data=toymi[[X]], y~x, pl=TRUE))

# CLIP confidence limits
PVR.confint(obj=fit.list)
```

sex2

Urinary Tract Infection in American College Students

Description

This data set deals with urinary tract infection in sexually active college women, along with covariate information on age and contraceptive use. The variables are all binary and coded in 1 (condition is present) and 0 (condition is absent).

Usage

sex2

Format

sex2: a data.frame containing 239 observations

case urinary tract infection, the study outcome variable

age ≥ 24 years

dia use of diaphragm

oc use of oral contraceptive

vic use of condom

viel use of lubricated condom

vis use of spermicide

sexagg

Urinary Tract Infection in American College Students

Description

This data set deals with urinary tract infection in sexually active college women, along with covariate information on age and contraceptive use. The variables are all binary and coded in 1 (condition is present) and 0 (condition is absent): case (urinary tract infection, the study outcome variable), age (≥ 24 years), dia (use of diaphragm), oc (use of oral contraceptive), vic (use of condom), viel (use of lubricated condom), and vis (use of spermicide).

Usage

sexagg

Format

sexagg: an aggregated data.frame containing 31 observations with case weights (COUNT).

case urinary tract infection, the study outcome variable

age ≥ 24 years

dia use of diaphragm

oc use of oral contraceptive

vic use of condom

viel use of lubricated condom

vis use of spermicide
